What This Project Is

A population health analytics dashboard that profiles and classifies 151,524 de-identified patient BMI records across Queensland hospital facilities, applying CDC classification standards to segment patients into Underweight, Healthy Weight, Overweight, and Obesity — for both adults and children, using the correct age-appropriate method for each.

This is a personal portfolio project demonstrating an end-to-end workflow: raw data → cleaning → clinical classification logic → relational data modelling → an interactive multi-page dashboard.

The Problem It's Solving

Raw patient weight data alone doesn't answer planning questions like which regions have the highest concentration of overweight/obese patients, whether the pattern is improving over time, or where a targeted intervention program would do the most good.

This dashboard turns raw, unclassified records into an actionable planning tool — the kind used to decide where to direct funding and intervention programs, rather than spreading resources evenly regardless of need.

The Dataset

151,524 raw patient records: facility, age, suburb, postcode, weight, height, BMI, and measurement date, spanning 2015-2021.

A second reference file provides CDC growth chart percentiles by age-in-months and gender, used for classifying children.

Known limitation: this data pull is 100% female patients — a property of the dataset, not a filter applied during analysis.

Data Cleaning

Removed records with implausible BMI (outside 8-90) or age (outside 0-105) — 314 of 151,524 raw records dropped (0.2%), leaving 151,210 clean records.

Built a single usable record date per patient, extracted Year for trend analysis, and bucketed patients into age groups (0-18 through 90-110).

BMI Classification — the Core Logic

Adults (≥20 years): fixed CDC cutoffs — Underweight <18.5, Healthy 18.5-24.9, Overweight 25.0-29.9, Obesity ≥30.0.

Children (2-19 years): CDC age- and gender-specific growth chart percentiles, since the same BMI value means something different at different ages — Underweight below 5th percentile, Healthy 5th-85th, Overweight 85th-95th, Obesity 95th and above.

Report Info

Dictionary

HSS / HHS

Hospital and Health Service. Queensland's regional public health service districts, used to group facilities by region for reporting.

BMI

Body Mass Index. $\text{Weight(kg)} \div \text{height(m)}^2$. Used as the basis for classifying patients into weight categories.

CDC

Centers for Disease Control and Prevention. Source of the adult BMI cutoffs and child growth-chart percentiles used to classify every patient in this dashboard.

Facility code

Short code identifying a specific hospital (e.g. PAH = Princess Alexandra Hospital, TTH = Townsville University Hospital).

Healthy Weight / Overweight / Obesity / Underweight

The four CDC classification categories every patient record is assigned to, based on BMI plus age (and, for children, gender).

Adult classification

Fixed BMI cutoffs applied to patients aged 20 and over.

Child classification

Age- and gender-specific percentile classification applied to patients aged 2–19, since a fixed BMI cutoff isn't clinically valid for growing children.

Healthy Weight %

Share of patient records in a given group (facility, region, age group, year) classified as Healthy Weight.

n / sample size

Number of patient records underlying a given percentage, shown throughout to flag results based on very few patients.

Other / Unmapped

A small number of facility codes that couldn't be confidently matched to a specific HSS region, disclosed rather than guessed.

HSS regions covered

Metro North, Metro South, Gold Coast, Sunshine Coast, Townsville, Mackay, West Moreton, and Children's Health — the regions represented in this dataset.
